

Amazon Connect Custom Contact Control Panel Intermediate

Course Summary

Benefits

The Amazon Connect Streams APIs offer organizations the ability to create custom agent experiences within their web applications. Streams offer access to real-time call and chat events, agent assist, and case management. Developers can meet various functional and business needs with Streams' support for multi-layered integrations.

Architecture

The Streams architecture comprises four layers:

- **Amazon Connect CTI Service:** Handles requests and raises events.
- **Application Integration:** Provides methods and event buses for integrating Amazon Connect functionality within external web applications.
- **CCP:** Authenticates agents and passes information between the application and the Connect Shared Worker.
- **Connect Shared Worker:** Synchronizes data across different service components, ensuring agent status and configuration updates are reflected across all open tabs, iframes, and connected application pages.

APIs

Core API: Developers can initialize the CCP, subscribe to events like `onload`, configure softphone settings, and customize the CCP's display in the settings tab. This API offers integration of the built-in CCP in external applications, and synchronization of agent and contact updates.

Agent API: The Agent API provides event subscription and methods to manage agent states. Developers handle events like state changes, routable or non-routable events, and errors. They can create handlers for state changes and agent availability. Additionally, the API can programmatically set the agent's availability using the `setState` method.

Contact API: The Contact API offers event subscription and methods to manage contact states. Developers handle events like `onIncoming`, `onConnected`, and `onEnded`, and performs actions such as answering or disconnecting calls. The API also programmatically retrieves contact details like caller name, phone number, and queue name.

Additional functionality

Customer Profiles

Amazon Connect Customer Profiles offers agents real-time access to customer data for personalized interactions. The functionality of Customer Profiles delivers capabilities such as search and display of relevant customer information. Developers can integrate this functionality using Streams with either the built-in, or a custom widget via the Customer Profiles JavaScript library.

Amazon Q in Connect

Amazon Connect Custom Contact Control Panel Intermediate

Course Summary

Amazon Q in Connect uses generative AI to suggest responses and actions, enhancing issue resolution and customer satisfaction. Developers can integrate this functionality into their applications using Streams. They can initialize the built-in Amazon Q in Connect widget or create a custom widget using the Amazon Q in Connect JavaScript library. The custom widget offers tailored recommendations based on the conversation and relevant knowledge content.

Step-by-Step Guides

Amazon Connect provides step-by-step guides that help agents navigate contact requests efficiently. Developers can embed guides into their applications using Streams. The guide displays when a contact connects, and stays visible until after-call work is done.
