

Amazon Connect Customer Profiles Getting Started

Course Summary

In this course, you learned about Amazon Connect Customer Profiles. It's a feature of Amazon Connect that helps improve agent productivity by combining customer information from source applications with customer data stored in Amazon Connect. It leverages combined customer data to create personalized customer experiences. You explored the benefits of this feature, and how to configure it, integrate source applications, and how to consolidate similar profiles with the Identity Resolution feature. Take a moment to review these key concepts in the course summary before taking the course assessment.

Benefits

Customer Profiles provides three key benefits to organizations.

Personalized,
dynamic
experience

Unified
View for
Agents

De-duplication
with Identity
Resolution

Personalized, dynamic experience: Customer Profiles lets organizations create personalized and dynamic customer experiences through IVR and chatbots. The technology behind these experiences is Amazon Connect Flows. Specifically, the Customer Profiles Flow block can be used to get, create, or update a customer's profile automatically. Organizations can use these tools to personalize automated interactions and contact routing—helping to increase customer trust and satisfaction.

Unified view for agents: Customer Profiles creates a single, unified view of customer information. This helps agents view all information in one place instead of toggling between applications to gather customer data. It does this by automatically scanning and matching the customer phone number or customer ID against information available in connected applications. It surfaces this collated information directly in Amazon Connect through the agent workspace. The single, unified view lets agents spend more time solving customer problems and reducing wait time for customers.

Deduplication with Identity Resolution: Since Customer Profiles makes it possible for organizations to bring over customer data from multiple sources, there might be duplicate records for the same contact. To solve this, organizations can activate the Identity Resolution feature of Customer Profiles, which runs an Identity Resolution Job on a weekly basis. Identity Resolution uses ML to automatically match similar profiles and put them into match groups. Organizations can also opt to automatically merge similar profiles. Automatic profile matching produces a confidence score between 0 and 1. The closer the confidence score is to 1 the higher the likelihood that the duplicate profiles are a match. The Identity Resolution Job writes the

Course Summary

results of the automatic profile matching process to the specified Amazon S3 bucket. You can create strong match criteria, for example, by selecting multiple attributes such as first, middle, and last name (instead of just the last name).

Concepts

Object type mapping: is a way to define how Customer Profiles will ingest a specific type of data from source applications. It also controls how Customer Profiles will read and map the ingested data from source applications into a standard profile object. Object type mapping can be created two different ways: using the Amazon Connect console user interface or the Customer Profiles API. It is important to plan how you want to map data, because you cannot choose a different mapping after completing the integration.

Identity Resolution: is a feature of Customer Profiles that uses ML to automatically detect and match similar profiles. The automatic profile matching process puts similar profiles into a group. Consolidation criteria can be used to optionally automatically merge similar profiles into a single, unified profile, which eliminates duplicate profiles. Agents with the appropriate security permissions can associate customers to existing profiles—reducing the number of profiles to sort through and creating a comprehensive, up-to-date view of customer information. Dead-letter queues can be used to view errors and send error messages using Amazon SQS. To view the profile IDs of customer profile potential matches that identity resolution has identified, you can download a file from the designated Amazon S3 bucket.

Domains and error reporting

Domain names are selected when the Customer Profiles feature is activated, which can happen when instances are first created or later on. Organizations are required to create an AWS KMS key to encrypt Customer Profiles data. For error-reporting purposes, organizations have the option to use a dead-letter queue to report errors associated with ingesting data from third-party applications, such as Salesforce, Marketo, and Segment.

Integrating Amazon Connect Customer Profiles

Customer Profiles makes integrating applications easy by using pre-built connectors powered by Amazon AppFlow and Amazon EventBridge.

Integrating applications with prebuilt connectors: Amazon Connect provides prebuilt connectors for external data source applications as well as internal sources. Prebuilt connectors provide convenient setup using a step-by-step guided process rather than having to code custom integrations using program languages or APIs.

Integrating applications without prebuilt connectors: Organizations can build their own custom integrations to programmatically sync customer data with Customer Profiles using the following developer tools:

Course Summary

- Amazon Connect Customer Profiles Rest API
- AWS CLI Command Reference for Customer Profiles
- AWS SDK for JavaScript v3
- Amazon Connect Streams API

The Customer Profiles Flow block

Amazon Connect uses Flows to personalize the customer experience from beginning to end. When the Customer Profiles Flow block is added to a Flow, it can retrieve, update, create and associate a customer profile. In order for agents to view a customer's profile when it's retrieved, they need to be assigned to a security profile that lets them view customer data. You can also reference the Customer Profile block's Response fields in the subsequent Flow blocks in the Flow to further personalize the customer experience.

Agent workspace

Customer Profiles is accessed through the agent workspace—a single, intuitive application that provides agents with the tools to resolve issues efficiently. To take advantage of the benefits that Customer Profiles offers, an administrator needs to activate the feature either during instance creation or later on. They also need to assign Customer Profiles permissions to an agent's security profile.

Amazon Connect Customer Profiles Getting Started

Course Summary

The view permission lets agents view customer information including product purchase history, contact history, and additional information such as cell phone number or shipping address. They may also copy the profile ID, search for profiles, associate contact records, and directly visit the contact's record page. Administrators can also activate profile editing and creation permissions. Be sure to apply the principle of least privilege as a data security best practice.

Considerations

There are a few considerations you should be aware of when using Customer Profiles:

Service quotas: AWS implements service quotas to provide highly available and reliable service to all customers, and protect you from unintentional spend. Unless otherwise specified, values for each quota are unique to each Region a service is deployed in. Customer Profiles has several default service quotas that set maximum values and expiration (in days) for certain quotas. Domain count, keys per object type, and expiration of objects and profiles are some examples.

Amazon Connect Customer Profiles Getting Started

Course Summary

Visit the [Service quotas section](#) of the Administrator Guide or your Amazon Connect instance in the AWS Management Console for more details on service quotas for Customer Profiles.

Security: Customer Profiles security permissions need to be assigned to an agent's security profile in order for them to either view, edit, or create Customer Profiles. Note that if you are using Customer Profiles, it is possible that customer data could be Personal Identifiable Information (PII). It is required for data to be encrypted in Customer Profiles (using an AWS KMS key) or a service-owned key. When syncing data periodically with an Amazon Connect service, data is encrypted using a customer managed key and stored temporarily for one month.

Pricing: Unique Customer Profiles ingested using identity resolution or third-party data are priced per profile per month. There is no charge for profiles that only contain data generated by usage of Amazon Connect. There is an additional incremental charge per profile per month for profiles that store over 100 objects. For more information on the pay as you go pricing model and pricing examples, please navigate to the [Amazon Connect pricing](#) web page.
