

Amazon Connect Flows Fundamentals

Course Summary

This course provides an introduction to Amazon Connect flows. Flows define customer journeys across various channels like voice, chat and tasks. It covers the different types of flows, their purposes, and how they are constructed using flow blocks within the visual flow designer interface.

Flows

Amazon Connect provides multiple types of flows, designed to support different use cases. The types of flows available, are:

- **Inbound flow:** Is the default flow type created when you select the "Create flow" button. Use this flow type to activate customer experiences for incoming contacts before transferring to a queue.
- **Customer queue flow:** Defines the experience customers have while waiting in a queue before connecting to an agent.
- **Customer hold flow:** Defines the experience a customer has while placed on hold by an agent during a voice call.
- **Customer whisper flow:** Allows defining the customer experience just before joining an agent.
- **Agent whisper flow:** Defines the agent experience just before receiving a contact from a customer.
- **Agent hold flow:** Defines the agent experience as part of an inbound voice contact while the call is placed on hold.
- **Agent transfer flow:** Defines the agent experience when transferring a contact to another agent.
- **Transfer to queue flow:** Defines the agent experience when transferring a contact to another queue.
- **Outbound whisper flow:** Defines the customer experience before agent interaction on outbound calls.
- **Disconnect flow:** Is an inbound flow that runs when an agent disconnects, and the customer remains connected.

Flow blocks

Flow blocks are visual representations of actions available in a flow. Customer and agent experience designers use flow blocks to create flows in the Amazon Connect flow designer.

flow blocks are organized into seven categories: **Interact, Set, Check, Analyze, Logic, Integrate, and Terminate.**

To configure a flow block, drag it onto the flow designer canvas, open the block settings, update and save the changes.

Flow designer

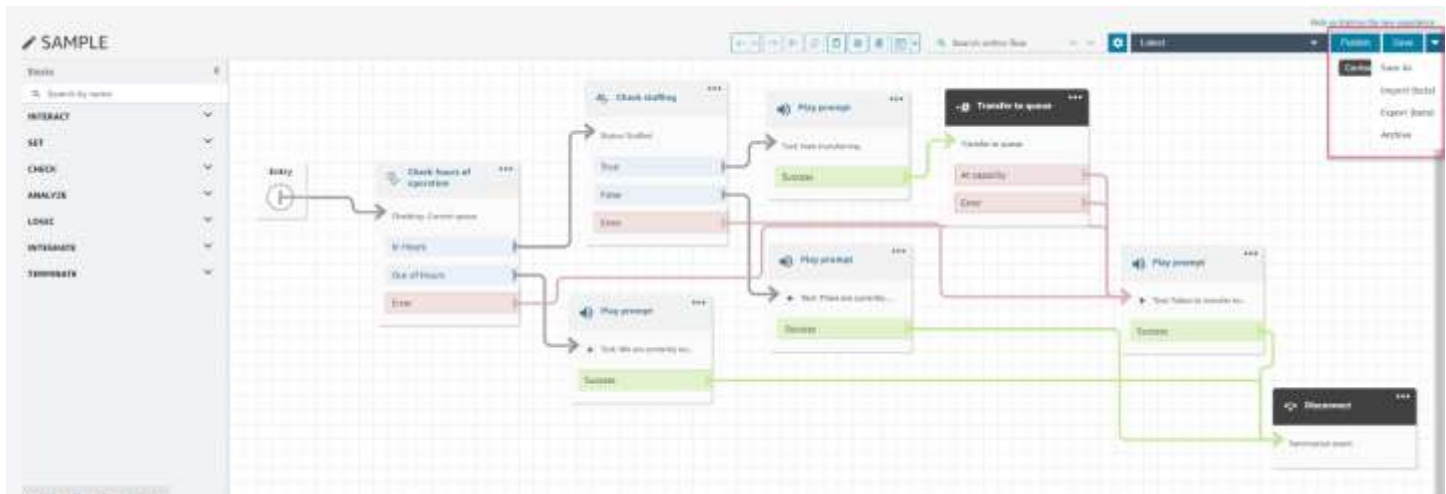

Amazon Connect Flows Fundamentals

Course Summary

The flow designer in Amazon Connect is a visual tool that allows creating and customizing contact center experiences.

Key capabilities include: designing flows, configuring flow logic, integrating with AWS services, testing and debugging flows, managing flow versions, and import and export flows.

The flow designer includes a toolbar with shortcuts to editing capabilities like searching flow blocks, undoing and redoing actions, cutting, copying, pasting, and deleting flow blocks.

Flow management

You can use the save, publish, and archive features of the flow designer to manage the IVR and agent experience.

Save your work as you design new custom flows or update existing flows. When ready to publish the flows to production, use the publish option.

Archive flows that are no longer required to be visible or exposed to production traffic for record-keeping purposes.

The flow designer maintains multiple versions of your flow when you publish it. You can also import and export flows.

Amazon Connect Flows Fundamentals

Course Summary

Enabling Amazon Connect functionality with flow blocks

You can activate specific Amazon Connect features within the flows, to tailor the customer journey according to your business requirements.

These features are:

- Call recording,
- Amazon Connect Contact Lens,
- Amazon Q in Connect,
- Amazon Connect Cases,
- Amazon Connect Tasks,
- Amazon Connect Customer Profiles, and
- Amazon Connect Persistent Chat.

To enable any of these features, search for the respective flow blocks, drag and drop them into the flow designer canvas, configure the block properties, and save the changes.

Operational Flow blocks

The **Distribute by percentage** block distributes incoming contacts randomly based on a specified percentage. You can use this block for testing strategies like blue/green deployments, to reduce risks when deploying new versions.

The **Set logging behavior** block enables tracking events as contacts interact with flows. Flow logs are stored in an Amazon CloudWatch log group. Configure CloudWatch to send alerts for unexpected events.
