

Amazon Connect Integrations Intermediate

Course Summary

Streaming contact events

Amazon Connect publishes contact events on an Amazon EventBridge bus. Contact events capture the lifecycle of a contact interaction. These events are published in near real-time. The events include contact initiation, connection to the system, queuing, agent connection, and disconnection. Contact events contain details like contact ID, channel, initiation method, agent information, and timestamps. Developers can create rules in EventBridge to capture and process these events.

The contact events data model includes general event information and event details. General information consists of resource identifiers, event version, ID, type, source, account, timestamp, and region.

Event details contain contact-specific data like initiation timestamp, channel, initiation method, agent information, and event type.

Queue and agent information is included when a contact is queued or connected to an agent.

Contact events can be used for analytics dashboards, workforce management integrations, and custom solutions like abandoned call recovery mechanisms.

Streaming agent events

Amazon Connect publishes agent events using Amazon Kinesis Data Streams. Agent events provide near real-time agent activity data. Developers can create dashboards, integrate with workforce management solutions, and configure alerts based on agent events.

Agent events include LOGIN, LOGOUT, STATE_CHANGE, and HEART_BEAT events. STATE_CHANGE events occur when an agent's status changes between routable and non-routable states. These events contain agent snapshots for current and previous states, as well as contact information when an agent is handling a contact.

Agent events data includes agent status, username, contact details, and timestamps. Developers can use this data to implement behavior specific to agent state changes and handle ongoing contact interactions.

Streaming Amazon Connect Contact Lens analytics

Amazon Connect Contact Lens offers real-time conversational analytics streaming through APIs. These APIs publish events for voice and chat interactions, enabling solutions for contact center efficiency.

For voice contacts, Contact Lens publishes STARTED, SEGMENTS, COMPLETED, and FAILED events. SEGMENTS events contain real-time analysis data like utterances, transcripts, matched categories, and sentiment analysis.

For chat contacts, the event types are similar, but the data model includes additional properties like output type, streaming settings, attachments, and system events. Real-time contact analysis events provide insights like sentiment scores, transcripts, and matched categories. Developers can aggregate sentiment scores and use the data for real-time widgets or translations.

Amazon Connect Integrations Intermediate

Course Summary

Streaming contact records

Amazon Connect streams contact records for completed interactions.

Contact records include metadata, agent information, performance metrics, recordings, and transcripts. Records are published at least once when a contact ends and are re-published upon updates.

Contact records contain general interaction information, contact details, agent details, queue details, disconnect reasons, and attached documents. Developers can use this data for auditing, reporting, and integrating with external systems.

Contact records are published to Amazon Kinesis Data Streams or Amazon Kinesis Firehose Delivery Streams. Data Streams are suitable for near real-time processing, while Firehose is suitable for single-purpose processing.

Integrating API Gateway with Amazon Connect

Amazon API Gateway enables creating, publishing, and maintaining APIs for services like Amazon Connect.

Integrating API Gateway with Amazon Connect allows building custom applications and interfaces that interact with Amazon Connect resources.

API Gateway can integrate with Amazon Connect using AWS service integration or AWS Lambda proxy. Service integration is suitable for direct API consumption, while Lambda proxy is suitable for complex, multi-step operations.

Developers can create REST endpoints in API Gateway that invoke Amazon Connect APIs or Lambda functions. This enables serverless applications and solutions, such as click-to-call functionality on websites.
