

Amazon Connect Routing Fundamentals

Course Summary

Benefits

Amazon Connect routing offers unified experiences across channels. Voice, chat, tasks, and SMS get routed through the same engine and queues. This approach optimizes contact outcomes and agent usage.

Routing can scale seamlessly without additional management overhead.

Queues

Amazon Connect has two queue types: standard and agent.

Standard queues hold contacts waiting for available agents. Administrators create standard queues based on skills, like product knowledge, or attributes, like geography.

Agent queues are automatically generated when users are created in the system. Use agent queues to route contacts to specific agents for personalized interactions.

Routing profiles, priorities and delays

A routing profile groups one or more queues matching agent skills and channels.

- Each agent has one routing profile that determines their eligibility for the available queues and channels.
- Within a routing profile, you can configure queue priorities and delays.
- The **priority** settings control the order in which queues get served.
- The **delay** settings expand the eligible agent pool as contacts age in queue.

Inbound and outbound routing

For **single channel routing**, consider the following:

- Contacts route through flows to queues based on agent routing profiles, queue hours, and flow logic.
- Metrics, like number of contacts in queue and oldest wait time, can influence routing decisions.
- Agents with available capacity receive contacts based on routing profiles, priorities, and contact age.

Multi-channel routing profiles configure concurrent channel settings, like handling one voice call or three chats. Cross-channel concurrency rules determine whether agents receive additional contacts across channels while engaged.

Outbound calls can be agent-initiated manually or programmatically routed after being dialed out.

Amazon Connect Routing Fundamentals

Course Summary

Built-in routing strategies

In **queue-based routing**, contacts get routed to agents based on the agent skills configured in routing profiles.

The **proficiency routing** configuration steps are as follows:

- Create predefined attributes for proficiency-based routing.
- Assign attributes to agents as proficiencies.
- Set routing criteria in flows to match contacts to proficient agents.
- Dynamically adjust contact queue priority and age.

Considerations

Service Quotas

Amazon Connect has default service quotas limits for: routing profiles, queues, quick connects, and predefined attributes per instance. Some quotas are adjustable.

Security

Grant permissions through security profiles following least privilege principles.

Security profiles control creating, editing, and viewing routing resources like profiles, queues, and attributes. Use tag-based access control to restrict access to specific tagged resources.
